

# Meter : 3-phase to sequence x,y

Meter : 3-phase to sequence x,y ..... 1

1 Description ..... 1

    1.1 Pins ..... 1

    1.2 Parameters ..... 1

    1.3 Input ..... 2

    1.4 Output ..... 2

## 1 Description

This device converts the first harmonic of the instantaneous value of 3 phase signals to the (x,y) coordinates of the corresponding zero-, positive-, and negative-sequence phasors in a reference frame rotating at the fundamental frequency.

### 1.1 Pins

This meter has nine pins:

<i>pin</i>	<i>type</i>	<i>description</i>	<i>units</i>
a	input pin	phase-a input signal	any
b	input pin	phase-b input signal	same as a
c	input pin	phase-c input signal	same as a
zero_x	output pin	x-coordinate of zero-sequence phasor	same as a
zero_y	output pin	y-coordinate of zero-sequence phasor	same as a
pos_x	output pin	x-coordinate of pos-sequence phasor	same as a
pos_y	output pin	y-coordinate of pos-sequence phasor	same as a
neg_x	output pin	x-coordinate of neg-sequence phasor	same as a
neg_y	output pin	y-coordinate of neg-sequence phasor	same as a

### 1.2 Parameters

The following parameter must be defined:

<i>parameter</i>	<i>description</i>	<i>units</i>
freq	fundamental frequency of the input signal	Hz

### 1.3 Input

The input pins may be connected to any control signals.  
The 3 signals are the instantaneous values of a 3-phase quantity.

### 1.4 Output

The outputs are the (x,y) phasor representation of the zero-, positive-, and negative-sequence transformations of the instantaneous values of the 3-phase input signals. The (x,y) coordinates are the x-axis and y-axis projections of the phasors on a reference frame rotating at the fundamental frequency.

The (x,y) coordinates of the phasors in that reference frame are calculated over a sliding time window of period equal to  $1/freq$ , as follows.

The (x,y) coordinates of the first harmonic of each input signal  $k$  are calculated as

$$\begin{aligned}x_k &= \frac{2}{\text{period}} \cdot \int_{t-\text{period}}^t in_k(t) \cdot \cos(2\pi \cdot \text{freq} \cdot t) \cdot dt \\y_k &= \frac{2}{\text{period}} \cdot \int_{t-\text{period}}^t -in_k(t) \cdot \sin(2\pi \cdot \text{freq} \cdot t) \cdot dt\end{aligned}\tag{1}$$

where the negative sign for  $y$  follows the engineering convention for an inductive (lagging) current to have a negative angle when phasor rotation is counterclockwise.

The (x,y) coordinates of the zero-sequence transformation are calculated as

$$\begin{aligned}\text{seq0}_x &= \frac{1}{3} \cdot (x_a + x_b + x_c) \\ \text{seq0}_y &= \frac{1}{3} \cdot (y_a + y_b + y_c)\end{aligned}\tag{2}$$

The (x,y) coordinates of the positive-sequence transformation are calculated as

$$\begin{aligned}\text{seq1}_x &= \frac{1}{3} \cdot (x_a + rx_b + r^2x_c) \\ \text{seq1}_y &= \frac{1}{3} \cdot (y_a + ry_b + r^2y_c)\end{aligned}\tag{3}$$

The (x,y) coordinates of the negative-sequence transformation are calculated as

$$\begin{aligned}\text{seq2}_x &= \frac{1}{3} \cdot (x_a + r^2x_b + rx_c) \\ \text{seq2}_y &= \frac{1}{3} \cdot (y_a + r^2y_b + ry_c)\end{aligned}\tag{4}$$

where  $r$  represents a phasor rotation of  $2\pi/3$ , and  $r^2$  a rotation of  $4\pi/3$ .
